COR 1088

## PROJECT CORONA

- L. Due to the requirement that has been generated by the rapid technological advancement by the Russians. a reconnaissance—intelligence satellite program that provides aerial reconnaissance in support of national intelligence objectives has been developed and is operational. This program is known as COROMA.
- 2. The system used to acquire this reconstinuance employs a two stage earth-circling satellite vehicle, the first stage being a Thorboost and the second stage a Lockheed Agena Engine. There is a recoverable nose come portion carried that returns exposed camera film to the earth's surface for intelligence photo exploitation.
- portions of China, and the estellite countries. Average ground resolution has been 20 to 25 feet on a side and approximately 3, 000, 000 square miles of this territory has been photographed where the cloud coverage has been Category III or better (clear to 4/8 cloud coverage). Major items of intelligence significance include new airfields, new activity, build up and defense strengthening of major missile test sites and construction areas, and new SAM locations. The system has also demonstrated a capability for obtaining photography with extremely lew sun angles.
- 4. Information to improve current maps and charte, target folders, and information to revise and support combat operations has also been obtained with this system. The data has augmented information available from other sources and should provide the basis for operational direction of other intelligence gathering activities.
- There are currently sleven scheduled missions, utilizing this system, remaining to be accomplished by I January 1962. During this period a new camera and film will be used that will improve the ground resolution and quality of the returned product.

- A follow-on program has recently been approved that will utilize the Ther-Agena recoverable payload vehicle which will carry the camera and film payload necessary to obtain stereographic photography. Six such missions have been approved and the first launching has been scheduled for the early spring of 1962.
- Operationally OPD has the capability to program the area over which the satellite chiele will operate the camera; has established secretary control and consequalization procedures to implement consequal decisions as to when the camera will operate or not operate; and has organized and tied together the necessary channels to obtain weather forecasts and briefings on which to base such command decisions.
- In addition to the CORONA program DPD is also engaged in certain operational activities of the ARCOM program. This program uses the same satellite vehicle and launch boost as the CORONA program and carries a film payload which is also recoverable. The primary mission of the ARGON vehicle is for geodetic servey and perpose, not as an intelligence gathering device. By charter agreement, DPD provides operational reports control procedures. Headquarters control room coverage and action, security precautions, cover inpute. communications, and obtains R&D assistance, PIC facilities, necessary political approval for ARCON missions. Vital field support is also provided.
